

# COMP547A Homework set #4

## Due Thursday December 1st, 2022, 23:59

### Exercises (from Katz and Lindell's book)

[5%]

4.7 Let  $F$  be a pseudorandom function. Show that the following MAC for messages of length  $2n$  is insecure: **Gen** outputs a uniform  $k \in \{0, 1\}^n$ . To authenticate a message  $m_1 \| m_2$  with  $|m_1| = |m_2| = n$ , compute the tag  $F_k(m_1) \| F_k(F_k(m_2))$ .

[5%]

4.13 We explore what happens when the basic CBC-MAC construction is used with messages of different lengths.

(a) Say the sender and receiver do not agree on the message length in advance (and so  $\text{Vrfy}_k(m, t) = 1$  iff  $t \stackrel{?}{=} \text{Mac}_k(m)$ , regardless of the length of  $m$ ), but the sender is careful to only authenticate messages of length  $2n$ . Show that an adversary can forge a valid tag on a message of length  $4n$ .

[5%]

(b) Say the receiver only accepts 3-block messages (so  $\text{Vrfy}_k(m, t) = 1$  only if  $m$  has length  $3n$  and  $t = \text{Mac}_k(m)$ ), but the sender authenticates messages of any length a multiple of  $n$ . Show that an adversary can forge a valid tag on a new message.

[5%]

4.14 Prove that the following modifications of basic CBC-MAC do not yield a secure MAC (even for fixed-length messages):

(b) A random initial block is used each time a message is authenticated. That is, change Construction 4.9 by choosing uniform  $t_0 \in \{0, 1\}^n$ , computing  $t_\ell$  as before, and then outputting the tag  $\langle t_0, t_\ell \rangle$ ; verification is done in the natural way.

[5%]

4.27 Define an appropriate notion of a  $\epsilon$ -secure *two-time* MAC, and give a construction that meets your definition.

### HOMEMADE Question: Achieving Rivest's private-key encryption from a Mac

[5%]

Provide a security definition of a **Mac** that makes the (bit-by-bit) private-key encryption scheme that Rivest described secure in the sense of indistinguishability in the presence of an eavesdropper.

More on back...

12.6 Consider the following public-key encryption scheme. The public key is  $(\mathbb{G}, q, g, h)$  and the private key is  $x$ , generated exactly as in the El Gamal encryption scheme. In order to encrypt a bit  $b$ , the sender does the following:

- (a) If  $b = 0$  then choose a uniform  $y \in \mathbb{Z}_q$  and compute  $c_1 := g^y$  and  $c_2 := h^y$ . The ciphertext is  $\langle c_1, c_2 \rangle$ .
- (b) If  $b = 1$  then choose independent uniform  $y, z \in \mathbb{Z}_q$ , compute  $c_1 := g^y$  and  $c_2 := g^z$ , and set the ciphertext equal to  $\langle c_1, c_2 \rangle$ .

Show that it is possible to decrypt efficiently given knowledge of  $x$ . Prove that this encryption scheme is CPA-secure if the decisional Diffie-Hellman problem is hard relative to  $\mathcal{G}$ .

**Hint:** Prove that if "not CPA-secure" then "DDH problem is efficiently solved".

12.7 Consider the following variant of El Gamal encryption. Let  $p = 2q + 1$ , let  $\mathbb{G}$  be the group of squares modulo  $p$  (so  $\mathbb{G}$  is a subgroup of  $\mathbb{Z}_p^*$  of order  $q$ ), and let  $g$  be a generator of  $\mathbb{G}$ . The private key is  $(\mathbb{G}, g, q, x)$  and the public key is  $(\mathbb{G}, g, q, h)$ , where  $h = g^x$  and  $x \in \mathbb{Z}_q$  is chosen uniformly. To encrypt a message  $m \in \mathbb{Z}_q$ , choose a uniform  $r \in \mathbb{Z}_q$ , compute  $c_1 = g^r \bmod p$  and  $c_2 = m + r \bmod q$ , and let the ciphertext be  $\langle c_1, c_2 \rangle$ . Is this scheme CPA-secure? Prove your answer.

**Add WeChat powcoder**

12.17 Say three users have RSA public keys  $\langle N_1, 3 \rangle$ ,  $\langle N_2, 3 \rangle$ , and  $\langle N_3, 3 \rangle$  (i.e., they all use  $e = 3$ ), with  $N_1 < N_2 < N_3$ . Consider the following method for sending the same message  $m \in \{0, 1\}^\ell$  to each of these parties: choose a uniform  $r \leftarrow \mathbb{Z}_{N_1}^*$ , and send to everyone the same ciphertext

$$\langle [r^3 \bmod N_1], [r^3 \bmod N_2], [r^3 \bmod N_3], H(r) \oplus m \rangle,$$

where  $H : \mathbb{Z}_{N_1}^* \rightarrow \{0, 1\}^\ell$ . Assume  $\|N_1\| = \|N_2\| = \|N_3\| = n \ll \ell$ .

- (a) Show that this is not CPA-secure, and an adversary can recover  $m$  from the ciphertext even when  $H$  is modeled as a random oracle.

**Hint:** See Section 12.5.1.

- (b) Show a simple way to fix this and get a CPA-secure method that transmits a ciphertext of length  $3\ell + \mathcal{O}(n)$ .
- (c) Show a better approach that is still CPA-secure but with a ciphertext of length  $\ell + \mathcal{O}(n)$ .

[5%]

13.1 Show that Construction 4.7 for constructing a variable-length MAC from any fixed-length MAC can also be used (with appropriate modifications) to construct a signature scheme for arbitrary-length messages from any signature scheme for messages of fixed length  $\ell(n) \geq n$ .

[5%]

[5%]

[5%]

[5%]

[5%]

13.5 Another approach (besides hashing) that has been explored to construct secure RSA-based signatures is to *encode* the message before applying the RSA permutation. Here the signer fixes a public encoding function  $\text{enc} : \{0, 1\}^\ell \rightarrow \mathbb{Z}_N^*$  as part of its public key, and the signature on a message  $m$  is  $\sigma := [\text{enc}(m)^d \bmod N]$ .

(a) How is verification performed in such a scheme?

(b) Suggest an appropriate encoding function for  $\ell \ll \|N\|$  that heuristically prevents the “no-message attack” described in Section 13.4.1.

(c) Show that encoded RSA is insecure if  $\text{enc}(m) = m \| 0^{\kappa/10}$  (where  $\kappa \stackrel{\text{def}}{=} \|N\|$ ,  $|m| \stackrel{\text{def}}{=} 4\kappa/5$ , and  $m$  is not the all-0 message). Assume  $e = 3$ .

(d) Show that encoded RSA is insecure for  $\text{enc}(m) = m \| 0 \| m$  (where  $|m| \stackrel{\text{def}}{=} (\|N\| - 2)/2$  and  $m$  is not the all-0 message). Assume  $e = 3$ .

(e) Show attacks in parts (c) and (d) for arbitrary  $e$ .

**HOMEMADE Question: Defeating Rivest**

Alice and Bob are a bit confused. They are going to use a Digital Signature scheme as a **Mac**. Let  $\Pi = (\text{Gen}, \text{Sign}, \text{Vrfy})$  be a deterministic digital signature scheme (such as hashed RSA for instance). They run  $\text{Gen}(1^n)$  to obtain  $(p_k, s_k)$  but only share and use  $s_k$  as the private-key of a **Mac**.

[5%]

(A) Let  $\Pi' = (\text{Gen}', \text{Mac}', \text{Vrfy}')$  be the **Mac** resulting from this idea. Used as a **Mac** they simply set  $t := \text{Mac}'_{s_k}(m) := \text{Sign}_{s_k}(m)$ . However, since they only use  $s_k$ , how will the receiver verify the message-tag pair  $(m, t)$ ? In other words, what is  $\text{Vrfy}'_{s_k}(m, t)$ ? Why did I underlined the word “deterministic” above?

[5%]

(B) Show that if  $\Pi$  is a digital signature scheme existentially unforgeable under an adaptive chosen-message attack then  $\Pi'$  is a Mac existentially unforgeable under an adaptive chosen-message attack (whether  $p_k$  is made public or not).

[5%]

(C) Imagine that Alice and Bob use  $\Pi'$  as above, and that  $p_k$  is disclosed publicly. Explain how this defeats Rivest’s argument seen in class that private-key authentication implies private-key encryption.
